(Received 5 March 2018; published 19 July 2018)

Building upon the results of R. Augusiak *et al.* [*Phys. Rev. Lett.* **115**, 030404 (2015)] we develop a general approach to the generation of genuinely entangled multipartite states of any number of parties from genuinely entangled states of a fixed number of parties, in particular, the bipartite entangled ones. In our approach, certain isometries whose output subspaces are either symmetric or genuinely entangled in some multipartite Hilbert spaces are applied to local subsystems of bipartite entangled or multipartite genuinely entangled quantum states. To prove that entanglement of the resulting states is indeed genuine we then introduce criteria allowing us to decide it efficiently. The construction is then exploited to provide examples of multipartite states that are genuinely entangled but not genuinely nonlocal, giving further illustration for the inequivalence between entanglement and nonlocality in the multiparticle scenario. It is also shown how to construct genuinely entangled states which are unsteerable across certain bipartite cuts.

I. INTRODUCTION

Quantum entanglement is a fascinating feature of composite physical systems. It not only shows that quantum physics drastically departs from classical physics, but, over the years, has also been turned into a key resource for a whole range of applications such as quantum teleportation [1] or quantum cryptography [2]. It may also give rise to yet another, stronger feature of composite quantum systems, which is Bell nonlocality [3]. Thus, detection and characterization of entanglement in composite quantum systems remains the central, but still unsolved, problem in quantum information theory [4].

With the development of experimental methods of generating, controlling, and manipulating quantum states consisting of more than two particles (see, e.g., Refs. [5,6]), the problem of entanglement detection and characterization has recently gained much importance. In comparison to the bipartite case, here this problem is complicated significantly by the fact that the multipartite scenario supports a whole variety of different types of entanglement (see Refs. [7–9] for various notions developed to grasp the richness of entanglement in the multipartite scenario). It turns out that of the broad variety of types of entanglement the most desirable one from the application point of view is the so-called genuine multipartite entanglement [10–12]. Roughly speaking, a state characterized by this type of entanglement is one in which all particles all entangled with each other; more formally, according to the operational definitions of separability, it is a state which cannot be created from scratch only using local operations and classical communication by spatially separated parties (the so-called LOCC paradigm). In recent years we have thus witnessed a considerable effort towards providing theoretical constructions of genuinely entangled states as well as

experimental realizations of various interesting states (see, e.g., Ref. [5]).

Our aim with this contribution is to shed light on this complex problem from a slightly different angle. Building upon our recent work [13], we provide a general method for constructing genuinely entangled N -partite states with any N from K -partite genuinely entangled states with $K < N$. In the particular, and at the same time the most interesting, case of $K = 2$ this method can be used to embed the known classes of entangled bipartite states to the multiparty case in such a way that the resulting state is genuinely entangled. Our construction consists of applying certain isometries whose output subspaces are either symmetric or genuinely entangled in multipartite Hilbert spaces to the local subsystems of the initial bipartite or K -partite density matrices. A key ingredient of our approach is certain entanglement criteria that we derive here which allow one to check whether a given multipartite state is genuinely entangled.

Then, following Ref. [13], we show how this construction can be harnessed to obtain examples of genuinely entangled N -partite states that are not genuinely nonlocal with respect to the Svetlichny and the recent operational definitions of nonlocality [14,15]. We thus obtain further examples of multipartite states illustrating the statement made in Ref. [13] that entanglement and nonlocality are inequivalent notions in the multipartite scenario (see also Ref. [16] for genuinely multipartite entangled states with fully local models). Finally, we show that these concepts can also be applied to the notion of steering in the multipartite case. In particular, we present examples of genuinely entangled states which are unsteerable across certain bipartitions.

The paper is organized as follows. In Sec. II we introduce some background information that is used throughout the

whole paper. In Sec. III we present our construction along with entanglement conditions and examples of genuinely entangled states obtained from the construction. In Sec. IV we show in a detailed way how our approach can be used to design genuinely entangled states for any number of parties that are not genuinely nonlocal. We then discuss an application of these concepts to steering in the multipartite scenario. We conclude in Sec. V.

II. PRELIMINARIES

This section sets up the scenario and introduces the relevant notation and terminology from the area of multipartite entanglement. The notions of (non)locality and (un)steerability in the relevant multipartite scenarios will be discussed in Sec. IV.

Consider N -parties $A_1, \dots, A_N := \mathbf{A}$ [for small N they will be denoted A (Alice), B (Bob), etc.] holding an N -partite quantum state described by the density matrix $\rho_{\mathbf{A}}$ acting on $\mathcal{H}_{d,N} := (\mathbb{C}^d)^{\otimes N}$, i.e., $\rho_{\mathbf{A}} \in \mathcal{B}((\mathbb{C}^d)^{\otimes N})$, where $\mathcal{B}(\mathcal{H})$ denotes the set of bounded linear operators acting on \mathcal{H} .

A division of the parties into K nonempty disjoint groups S_i (the number of elements in S_i will be denoted by $|S_i|$) such that $S_1 \cup \dots \cup S_K = \mathbf{A}$ is called a K -partition, denoted by $S_1|S_2|\dots|S_K$ or simply S_K ; when $K = 2$ such division is called a *bipartition* and denoted simply by $S|\bar{S}$, where \bar{S} is the complement of S in \mathbf{A} . The set of all K -partitions will be denoted by \mathbb{S}_K .

Any K -partition induces a natural K -partition of $\mathcal{H}_{d,N}$ into the corresponding subsystems, i.e., $\mathcal{H} = \bigotimes_{p=1}^K \mathcal{H}_{S_p}$ with \mathcal{H}_{S_p} being the Hilbert space corresponding to the parties from the set S_p .

Now, a state is called K -separable with respect to some K -partition $S_1|S_2|\dots|S_K$ if it is a convex combination of pure states from $\mathcal{H}_{d,N}$ that are product with respect to this K -partition, i.e.,

$$\rho_{S_K} = \sum_i p_i |\psi_{S_1}^i\rangle\langle\psi_{S_1}^i| \otimes |\psi_{S_2}^i\rangle\langle\psi_{S_2}^i| \otimes \dots \otimes |\psi_{S_K}^i\rangle\langle\psi_{S_K}^i|, \quad (1)$$

where $|\psi_{S_j}^i\rangle$ are pure states belonging to the Hilbert space corresponding to the group S_j , i.e., $|\psi_{S_j}^i\rangle \in \mathcal{H}_{S_j}$. Then, we simply call an N -partite state $\rho_{\mathbf{A}}$ K -separable if it is a convex combination of quantum states that are K -separable across various K -partitions, which mathematically can be expressed as

$$\rho_{\mathbf{A}} = \sum_{S_K \in \mathbb{S}_K} q_{S_K} \rho_{S_K}, \quad (2)$$

where $\{q_{S_K}\}$ is a probability distribution, whereas ρ_{S_K} are mixed states separable with respect to a particular K -partition S_K ; i.e., they admit the decomposition (1). In the particular case of $K = 2$ one speaks about the *biseparability* of states. Importantly, any $(K + 1)$ -separable state is also K -separable.

At one end of the above classification there are states that are N -separable ($K = N$ case); we call them *fully separable* because no entanglement whatsoever is present in such states. At the other end, one has *genuine multipartite entangled* (GME) states which are those that do not decompose into any probabilistic mixture of states that admit any form of

separability, even biseparable ones. In short, GME states are those which are not biseparable.

In what follows particular attention will be devoted to certain subspaces. The first one is the symmetric subspace of $\mathcal{H}_{d,N}$, denoted $\text{Sym}((\mathbb{C}^d)^{\otimes N})$. It consists of vectors that are invariant under permutation of any pair of parties and its dimension is $\binom{N+d-1}{d-1}$, which for qubits simplifies to $N + 1$. It is worth mentioning that in the particular case of $\mathcal{H}_{2,N}$, $\text{Sym}((\mathbb{C}^2)^{\otimes N})$ is spanned by the so-called symmetric Dicke states $|D_{N,k}\rangle$ which are normalized symmetrizations of the simple kets $|\{N,k\}\rangle$ consisting of k ones and $N - k$ zeros, i.e.,

$$|D_{N,k}\rangle = \frac{1}{\sqrt{\binom{N}{k}}} \text{Sym}(|0\dots 01\dots 1\rangle), \quad (3)$$

where Sym stands for the said symmetrization. For further benefit, let us also note that $\text{Sym}((\mathbb{C}^2)^{\otimes N})$ contains either fully product vectors $|e\rangle^{\otimes N}$ with $|e\rangle \in \mathbb{C}^2$ or genuinely entangled ones. A word about the terminology regarding symmetric subspaces used in the rest of the paper is in order: when we say that a subspace is symmetric we mean that either it is the symmetric subspace, $\text{Sym}((\mathbb{C}^d)^{\otimes N})$, itself or it is simply a subspace of the latter.

We will then consider subspaces consisting solely of multipartite states that are genuinely multipartite entangled. Such subspaces, which can naturally be called *genuinely entangled subspaces* (GESs), were first mentioned in Ref. [17]; however, since then, they have been barely studied in the literature. A well-known example of a genuinely entangled subspace is the antisymmetric subspace in $\mathcal{H}_{d,N}$ for $d \geq N$. It is spanned by entangled vectors that acquire the minus sign under permutation of any pair of parties and its dimension is $\binom{d}{N}$. A recent effort towards characterization of such genuinely entangled subspaces has been reported in Ref. [18]. Let us finally note that GESs belong to a larger class of subspaces called *completely entangled subspaces* (CESs) [17,19–21], which only contain entangled vectors, however, not necessarily genuinely entangled. Consequently, a GES is also a CES; however, the opposite implication does not hold in general.

Projections onto the subspaces discussed above will be denoted by $P_{S_i}^{\text{sym}}$ and $P_{S_i}^{\text{ges}}$, accordingly, with a subscript indicating subsystems they act on.

III. GENERATING N -PARTITE GME STATES FROM K -PARTITE GME STATES WITH $K < N$

The aim of this section is to introduce, building upon the results of Ref. [13], a simple method of generating N -partite genuinely entangled states from K -partite GME states with $K < N$. In the particular case of $K = 2$ the method allows for an extension of bipartite entangled states to GME states of *any* number of parties. In further parts, this method will be employed to construct new examples of genuinely entangled multipartite states that are not genuinely multipartite nonlocal, and also use it to provide examples of GME states that are unsteerable with respect to certain cuts.

A. Entanglement conditions

Our construction of GME states relies heavily on entanglement conditions, which are generalizations of the criterion

formulated in [13]. For completeness, we recall it along with its proof below. The latter requires a lemma about a certain property of product vectors with symmetric subsystems. The proof is given in the Appendix.

Lemma 1 [13]. Let $|\psi\rangle \in \mathcal{H}_{d,N}$ be a pure state which is product with respect to a certain bipartition $T|\bar{T}$. If $P_S^{\text{sym}}|\psi\rangle = |\psi\rangle$ where S is a subset of \mathbf{A} having nontrivial overlaps with T and \bar{T} , i.e., $S \cap T \neq \emptyset$ and $S \cap \bar{T} \neq \emptyset$, then $|\psi\rangle$ is also product with respect to the bipartition $S|\bar{S}$.

We can now give the announced condition from [13].

Fact 1 [13]. Let $\rho_{\mathbf{A}}$ be an N -partite state acting on $\mathcal{H}_{d,N}$ such that with respect to a certain K -partition $S_1|S_2|\dots|S_K$, its subsystems corresponding to S_k 's are supported on the symmetric subspaces, i.e.,

$$P_{S_1}^{\text{sym}} \otimes \dots \otimes P_{S_K}^{\text{sym}} \rho_{\mathbf{A}} P_{S_1}^{\text{sym}} \otimes \dots \otimes P_{S_K}^{\text{sym}} = \rho_{\mathbf{A}}. \quad (4)$$

Then, if $\rho_{\mathbf{A}}$ is not GME, it takes the biseparable form

$$\rho_{\mathbf{A}} = \sum_{T|\bar{T}} p_{T|\bar{T}} \rho_{T|\bar{T}}^{\text{sep}}, \quad (5)$$

where the sum runs over all bipartitions $T|\bar{T}$ for which T and \bar{T} are unions of the sets S_k and $\rho_{T|\bar{T}}^{\text{sep}}$'s are separable across $T|\bar{T}$.

Proof. Since ρ is not GME it admits the biseparable ($K = 2$) decomposition (2). Assume then that in this decomposition there is a biseparable state $\rho_{T|\bar{T}}$ where T , and, in consequence, also \bar{T} , are *not* unions of the sets S_k . Obviously, such $\rho_{T|\bar{T}}$ admits the decomposition (1) in which there only appear pure states that are products with respect to $T|\bar{T}$, but not with respect to sets that are unions of S_k , by the assumption above.

Let $|\psi_T\rangle|\phi_{\bar{T}}\rangle$ be any of such product states. Now, since T is not a union of S_k 's, there exists at least one set among the latter whose overlap with both T and \bar{T} is nonempty. Further, for at least one such set, say S_{i_m} , either the state $|\psi_T\rangle$ is not product with respect to the bipartition $(T \cap S_{i_m})|[T \setminus (T \cap S_{i_m})]$ or $|\phi_{\bar{T}}\rangle$ is not product with respect to the bipartition $(\bar{T} \cap S_{i_m})|[\bar{T} \setminus (\bar{T} \cap S_{i_m})]$, as otherwise $|\psi_T\rangle|\phi_{\bar{T}}\rangle$ would be product with respect to unions of the sets S_k . This, via Lemma 1, implies that the condition $P_{S_{i_m}}^{\text{sym}}|\psi\rangle = |\psi\rangle$ cannot be satisfied, which, in turn, contradicts (4). This completes the proof. ■

Two remarks are in order here. First, if $K = 2$, i.e., the state $\rho_{\mathbf{A}}$ can be regarded as having two subsystems S and \bar{S} defined on the symmetric subspaces of the corresponding Hilbert spaces, then Eq. (5) simplifies to

$$\rho_{\mathbf{A}} = \sum_i p_i \rho_S^i \otimes \rho_{\bar{S}}^i; \quad (6)$$

that is, the state $\rho_{\mathbf{A}}$ is simply separable across the bipartition $S|\bar{S}$. Second, a straightforward corollary of this fact is a condition for a multipartite state to be genuinely entangled.

Corollary 1 [13]. If ρ satisfies (4) and does not admit the decomposition (5), then it is genuinely multipartite entangled. In particular, for $K = 2$, if ρ is entangled across the bipartition $S|\bar{S}$, then it is GME.

This gives a simple method of checking whether a state is genuinely entangled: once we know that ρ has the symmetry (4), one has to check only some of the bipartitions to confirm that ρ is GME. The existence of this symmetry may be given in advance or verified with a direct computation.

We now move on to derive generalizations of the above fact. For this purpose, let us note that the key property of the symmetric subspaces that enabled us to prove Fact 1 is that they only consist of either fully product vectors or multipartite states that are genuinely entangled (see, e.g., Refs. [22,23]). This observation can be further exploited to extend Fact 1 to other types of subspaces. Precisely, as we demonstrate below, the symmetric subspaces in (4) can be replaced by arbitrary genuinely entangled subspaces of \mathcal{H}_{S_i} .

For pedagogical reasons we begin with the case of $K = 2$ and consider a certain bipartition $S|\bar{S}$ of the Hilbert space $\mathcal{H}_{d,N} = \mathcal{H}_S \otimes \mathcal{H}_{\bar{S}}$ ($|S| + |\bar{S}| = N$). Let us then distinguish two genuinely entangled subspaces of the Hilbert spaces corresponding to the groups S and \bar{S} , $\mathcal{V}_{\text{ges}} \subset \mathcal{H}_{d,|S|}$ and $\mathcal{V}'_{\text{ges}} \subset \mathcal{H}_{d,|\bar{S}|}$, with the projections P_S^{ges} and $P_{\bar{S}}^{\text{ges}}$, respectively. The following holds true.

Fact 2. Let $\rho_{\mathbf{A}}$ be an N -partite state acting on $\mathcal{H}_{d,N}$ such that there exist a bipartition $S|\bar{S}$ for which the following condition holds,

$$P_S^{\text{ges}} \otimes P_{\bar{S}}^{\text{ges}} \rho_{\mathbf{A}} P_S^{\text{ges}} \otimes P_{\bar{S}}^{\text{ges}} = \rho_{\mathbf{A}}. \quad (7)$$

If $\rho_{\mathbf{A}}$ is not GME, then it is separable across the bipartition $S|\bar{S}$.

Proof. The fact that $\rho_{\mathbf{A}}$ is not GME implies that it can be written as a convex combination of states that are biseparable across various bipartitions. Assume then that in this decomposition there is a state that is biseparable across a bipartition $T|\bar{T}$ different from $S|\bar{S}$ (and that it is not separable across $S|\bar{S}$). It is not difficult to see that the range of this state contains product vectors $|\psi_{T|\bar{T}}\rangle = |\phi_T\rangle|\phi_{\bar{T}}\rangle$ which obey the symmetry (7), meaning that

$$P_X^{\text{ges}} |\psi_{T|\bar{T}}\rangle = |\psi_{T|\bar{T}}\rangle \quad (X = S, \bar{S}). \quad (8)$$

Let us now use the fact that the separability cut of $|\psi_{T|\bar{T}}\rangle$ belongs to S or \bar{S} ; otherwise these must be the same bipartitions. For concreteness we assume the latter to be S . Then, by tracing out the \bar{S} part of $|\phi_T\rangle|\phi_{\bar{T}}\rangle$ we obtain a mixed state ρ_S acting on the Hilbert space corresponding to the group S , which is biseparable. This contradicts the fact that, according to (8), $P_S^{\text{ges}} \rho_S P_S^{\text{ges}} = \rho_S$, meaning that ρ_S must be genuinely multipartite entangled. ■

We thus obtain another separability condition:

Corollary 2. If a multipartite $\rho_{\mathbf{A}}$ is entangled across a given bipartition $S|\bar{S}$ and satisfies (7), then it is GME.

It is not difficult to realize that Fact 2 can also be formulated more generally, just as Fact 1, for any K -partition with arbitrary K .

Moreover, Fact 1 and Fact 2 with its discussed extension can be combined into a more general statement, in which for every subset S_i of the parties, the related subspace of the corresponding Hilbert space can either be genuinely entangled or symmetric. Namely, the following holds.

Fact 3. Let $\rho_{\mathbf{A}}$ be an N -partite state acting on $\mathcal{H}_{d,N}$ such that there exists a K -partition $S_1|\dots|S_K$ of the parties for which the following holds true,

$$P_{S_1} \otimes \dots \otimes P_{S_K} \rho_{\mathbf{A}} P_{S_1} \otimes \dots \otimes P_{S_K} = \rho_{\mathbf{A}}, \quad (9)$$

where P_{S_i} stands for a projector onto a symmetric or genuinely entangled subspace of the Hilbert space corresponding to the group S_i .

Then, if ρ_A is not GME, it can be written as in Eq. (5) with T being sums of the sets S_i .

Proof. The proof follows similar lines of reasoning as that of Fact 2. Since ρ_A is not GME it admits the decomposition into a convex combination of biseparable states (5). Assume then that in this decomposition there is a biseparable state $\rho_{T|\bar{T}}$ for which T is not a union of some of the sets S_1, \dots, S_K . Clearly, this $\rho_{T|\bar{T}}$ can be written as the following convex combination,

$$\rho_T = \sum_i q_i |\psi_T^i\rangle\langle\psi_T^i| \otimes |\phi_{\bar{T}}^i\rangle\langle\phi_{\bar{T}}^i|, \quad (10)$$

in which at least one of the pure states $|\psi_T^i\rangle\langle\psi_T^i|$ is not product with respect to unions of the sets S_k .

Let us then consider one such state and denote it simply by $|\psi_T\rangle\langle\psi_T|$. Due to the fact that T is not a union of S_k 's there are sets S_{i_1}, \dots, S_{i_l} ($l \geq 1$; it is possible that there is only one such state), which have nonempty overlaps with both T and \bar{T} .

Let us denote by \mathcal{V}_i subspaces with respective projection P_{S_i} . We now need to consider two cases: (i) at least one of the subspaces $\mathcal{V}_{i_1}, \dots, \mathcal{V}_{i_l}$ is genuinely entangled; (ii) all of them are symmetric.

In the case (i), the fact that one of $\mathcal{V}_{i_1}, \dots, \mathcal{V}_{i_l}$, say \mathcal{V}_{i_m} , is genuinely entangled contradicts the condition (9). This is because the marginal density matrix $\rho_{S_{i_m}}$ of $|\psi_T\rangle\langle\psi_T|$ corresponding to the subset S_{i_m} is certainly separable across the bipartition $[T \cap S_{i_m}][\bar{T} \cap S_{i_m}]$, while the condition (9) implies that $P_{S_{i_m}}\rho_{S_{i_m}}P_{S_{i_m}} = \rho_{S_{i_m}}$, meaning that it must be supported on a genuinely entangled subspace.

As to the case (ii), we note that among the sets S_{i_1}, \dots, S_{i_l} there must be at least one, call it S_{i_m} , for which either the state $|\psi_T\rangle$ is not product with respect to the bipartition $(T \cap S_{i_m})|[T \setminus (T \cap S_{i_m})]$ or $|\phi_{\bar{T}}\rangle$ is not product with respect to the bipartition $(\bar{T} \cap S_{i_m})|[\bar{T} \setminus (\bar{T} \cap S_{i_m})]$. This, via Lemma 1, implies that the condition $P_{S_{i_m}}^{\text{sym}}|\psi_T\rangle\langle\psi_T| = |\psi_T\rangle\langle\psi_T|$ cannot be satisfied which contradicts (4). This completes the proof. ■

The above fact, with Facts 1 and 2 as special cases, is one of the main results of the present paper. It is the key ingredient of the construction of novel examples of states that are genuinely entangled but not genuinely nonlocal presented in the upcoming section.

Note that we could easily generalize the fact to the case of subspaces which contain either genuinely entangled states or fully product ones. As noted earlier, the symmetric subspace bears this feature, but clearly it is not the unique one possessing this property.

B. The construction

Having the above observations at hand, we can now pass to the announced construction of multipartite genuinely entangled states.

We begin with the simplest, yet probably the most interesting case of bipartite states ($K = 2$) extended to N -partite ones.

Consider a bipartite state ρ_{AB} acting on $\mathcal{H}_{d,2}$ and a pair of positive (P) trace preserving (TP) maps¹

$$\Lambda_A : \mathcal{B}(\mathcal{H}_{d,1}) \rightarrow \mathcal{B}(\mathcal{V}_1), \quad \Lambda_B : \mathcal{B}(\mathcal{H}_{d,1}) \rightarrow \mathcal{B}(\mathcal{V}_2), \quad (11)$$

where $\mathcal{V}_1 \subseteq \mathcal{H}_{d,|S|}$ and $\mathcal{V}_2 \subseteq \mathcal{H}_{d',|\bar{S}|}$ are subspaces belonging to $|S|$ -partite and $|\bar{S}|$ -partite Hilbert spaces of dimensions d and d' , respectively, and $|S| + |\bar{S}| = N > 2$. In general, the dimensions can be different; for clarity, however, in further parts of the paper we concentrate on the case $d = d'$. Of course, one could also consider a more general case with the local dimensions differing within each Hilbert space; nevertheless, such generalization is rather straightforward, and it would unnecessarily complicate the considerations without providing any additional significant insight. We thus do not consider it here. We intentionally begin with a quite general class of PTP maps, as this will be useful later; however, by imposing further constraints on them we will recover the class of maps that can be used in our construction.

Let us now assume that the simultaneous action of both Λ_A and Λ_B on the respective subsystems of the state ρ_{AB} results in a positive operator, i.e., $(\Lambda_A \otimes \Lambda_B)(\rho_{AB}) \geq 0$, and consider the resulting N -partite quantum state

$$\sigma_A = (\Lambda_A \otimes \Lambda_B)(\rho_{AB}). \quad (12)$$

Note here that we allow for the situation that one of the sets S or \bar{S} contains only one element, meaning that the output Hilbert space of this map is single-partite, and the state ρ_{AB} is not expanded on this subsystem.

Finally, we will need to assume that (i) both PTP maps Λ_A and Λ_B are invertible, which means that there exist $\Lambda_A^{-1} : \mathcal{B}(\mathcal{V}_1) \rightarrow \mathcal{B}(\mathcal{H}_{d,1})$ and $\Lambda_B^{-1} : \mathcal{B}(\mathcal{V}_2) \rightarrow \mathcal{B}(\mathcal{H}_{d,1})$ such that $\Lambda_X^{-1}(\Lambda_X(Z)) = Z$ for any Z and with $X = A, B$, and (ii) both inverses are positive too. This is a strong assumption as it is known that PTP maps have positive inverses in the above sense iff they are isometric conjugations, i.e., $\Lambda_X(\cdot) = V(\cdot)V^\dagger$ with V satisfying $V^\dagger V = \mathbb{1}_d$, or transpositions (see Corollary 6.2 of Ref. [24]). In what follows, for obvious reasons, we only focus on the first type of mappings and on many occasions call them shortly isometries.

With all this at hand we can now state our second of the main results, which is a generalization of the one proven in Ref. [13].

Theorem 3. Consider a bipartite entangled state ρ_{AB} acting on $\mathcal{H}_{2,d}$ and two subspaces $\mathcal{V}_1 \subseteq \mathcal{H}_{|S|,d'}$ and $\mathcal{V}_2 \subseteq \mathcal{H}_{|\bar{S}|,d'}$ in some $|S|$ - and $|\bar{S}|$ -partite Hilbert spaces of local dimension d' such that $|S| + |\bar{S}| = N > 2$. Each subspace is assumed to be either symmetric or genuinely entangled in the corresponding Hilbert space. Then, the N -partite state (12) with Λ_A and Λ_B being isometric mappings is GME.

Proof. Let us assume the contrary, i.e., that σ_A is not GME. Due to the fact that the output subspaces of the positive maps Λ_i are either symmetric or genuinely entangled, Fact 3 tells us that σ must be separable across the bipartition $S|\bar{S}$, i.e.,

$$\sigma_A = (\Lambda_A \otimes \Lambda_B)(\rho_{AB}) = \sum_i q_i \rho_S^i \otimes \rho_{\bar{S}}^i. \quad (13)$$

¹A linear map $\Lambda : \mathcal{B}(\mathcal{H}) \rightarrow \mathcal{B}(\mathcal{K})$ is positive if when applied to a positive operator it returns a positive operator.

Since Λ_A and Λ_B are invertible, we can express the state ρ_{AB} as

$$\rho_{AB} = \sum_i q_i \Lambda_A^{-1}(\rho_S^i) \otimes \Lambda_B^{-1}(\rho_S^i). \quad (14)$$

Since Λ_X^{-1} ($X = A, B$) are positive too, this leads to a contradiction with the assumption that ρ_{AB} is entangled. ■

It turns out that this statement can be generalized to $K > 2$; i.e., as the initial state we can use K -partite states that are genuinely entangled. We have the following.

Theorem 4. Let $\rho_{A_1 \dots A_K}$ be a K -partite GME state. Consider a collection of isometries:

$$\Lambda : \mathcal{B}(\mathcal{H}_{A_i}) \rightarrow \mathcal{B}(\mathcal{V}_i) \quad (i = 1, \dots, K), \quad (15)$$

where each \mathcal{V}_i is assumed to be either a symmetric or a genuinely entangled subspace of the $|S_i|$ -partite subspace $\mathcal{H}_{S_i} = \mathcal{H}_{|S_i|, d'} = (\mathbb{C}^{d'})^{\otimes |S_i|}$ ($|S_1| + \dots + |S_K| = N$) corresponding to the group of parties S_i .

Then, the state

$$\sigma_A = (\Lambda_1 \otimes \dots \otimes \Lambda_K)(\rho_{A_1 \dots A_K}) \quad (16)$$

is GME.

Proof. Assume that the resulting state σ_A is not GME. Due to the fact that the output subspaces of the positive maps Λ_i are either symmetric or genuinely entangled, Fact 3 tells us that σ_A must be a convex combination of states that are separable across certain bipartitions $T|\bar{T}$, where T are unions of the sets S_i [see Eq. (5)]. Then, since all maps Λ_i are isometries, this would mean that the “initial” state $\rho_{A_1 \dots A_K}$ is not GME, which contradicts the assumption of the theorem. ■

We thus have a quite general construction of N -partite GME states from K -partite GME ones with $K < N$. Below, we demonstrate how the method works in practice, constructing a few examples of noisy multipartite states that are genuinely entangled.

C. Examples

Let us now illustrate our method by applying it to a few paradigmatic classes of states.

Example 1. Let us begin with an example considered already in Ref. [13] which concerns the well-known class of isotropic states [25]:

$$\rho_{\text{iso}}(p) = p|\phi_d^+\rangle\langle\phi_d^+| + (1-p)\frac{\mathbb{1} \otimes \mathbb{1}}{d^2} \quad (0 \leq p \leq 1), \quad (17)$$

where $|\phi_d^+\rangle = (1/\sqrt{d})\sum_{i=0}^{d-1}|ii\rangle$ is the maximally entangled state of two qudits, while $\mathbb{1}$ is a $d \times d$ identity matrix. For the maps Λ_X we then take rank-one (i.e., with a single Kraus operator) completely positive maps given as $\Lambda_A(\cdot) = V_L(\cdot)V_L^\dagger$ and $\Lambda_B(\cdot) = V_{N-L}(\cdot)V_{N-L}^\dagger$ with V_L being an isometry defined as

$$V_L|i\rangle = |i\rangle^{\otimes L}, \quad (18)$$

where $\{|i\rangle\}$ is the computational basis in \mathbb{C}^d . The output subspaces of both channels are certain subspaces of $\text{Sym}((\mathbb{C}^d)^{\otimes L})$ and $\text{Sym}((\mathbb{C}^d)^{\otimes(N-L)})$, respectively, and therefore our results can be applied here. An application of the isometries (18) to

$\rho_{\text{iso}}(p)$ results in the following class of N -qudit states,

$$\rho_N(p) = p|\text{GHZ}_{d,N}^{(+)}\rangle\langle\text{GHZ}_{d,N}^{(+)}| + (1-p)\frac{\mathcal{P}_{d,L} \otimes \mathcal{P}_{d,N-L}}{d^2}, \quad (19)$$

with $|\text{GHZ}_{d,N}^{(+)}\rangle = (1/\sqrt{d})\sum_{i=0}^{d-1}|i\rangle^{\otimes N}$ being the well-known d -level GHZ state and $\mathcal{P}_{d,L} = \sum_{i=0}^{d-1}|i\rangle\langle i|^{\otimes L}$. The states $\rho_N(p)$ are GME for any p for which the isotropic states are entangled, i.e., $p > 1/(d+1)$.

We now present a different extension of the isotropic state being an illustration to Theorem 3. With this aim consider the n qubit GES from Ref. [18] spanned by the unnormalized vectors:

$$|0\rangle \sum_{k=2}^n |(2^{n-k} + j)_2\rangle - |1\rangle|j\rangle_2, \quad j = 0, 1, \dots, 2^{n-2} - 1, \quad (20)$$

where $(\cdot)_2$ is the $(n-1)$ digit binary representation of a number. Assume that an orthonormal basis for this GES is $\{|\phi_j\rangle\}_{j=0}^{2^{n-2}-1}$. Set now $d = 2^{n-2}$ and consider the following isometries with the output in the GES:

$$V_n|j\rangle = |\phi_j\rangle, \quad 0 \leq j \leq 2^{n-2} - 1. \quad (21)$$

Applying locally such isometries to A and B of (17) gives the following $2n$ qubit state:

$$\hat{\rho}_{2n}(p) = p|\Phi_{\text{GES}}^+\rangle\langle\Phi_{\text{GES}}^+| + (1-p)\frac{\mathcal{P}_{\text{GES}} \otimes \mathcal{P}_{\text{GES}}}{2^{2n-4}}, \quad (22)$$

where $|\Phi_{\text{GES}}^+\rangle = (1/\sqrt{2^{n-2}-1})\sum_{j=0}^{2^{n-2}-1}|\phi_j\rangle|\phi_j\rangle$ and $\mathcal{P}_{\text{GES}} = \sum_{j=0}^{2^{n-2}-1}|\phi_j\rangle\langle\phi_j|$ is the projection on the GES under scrutiny. Reasoning as above, we have that $\hat{\rho}_{2n}(p)$ is GME for $p > 1/(2^{n-2}-1)$.

As an example consider the case $n = 3$. Then, the GES is spanned by

$$|\phi_0\rangle = \frac{1}{\sqrt{3}}(|001\rangle + |010\rangle - |100\rangle), \quad (23)$$

$$|\phi_1\rangle = \frac{1}{\sqrt{6}}\left(\frac{3}{2}|001\rangle + |010\rangle - \frac{1}{2}|011\rangle - \frac{3}{2}|100\rangle + \frac{1}{2}|101\rangle\right). \quad (24)$$

Example 2. Building on the above example we can construct a more general class of GME states. Consider any pure entangled state of two qudits written in the Schmidt form as

$$|\psi_\mu\rangle = \sum_{i=0}^{d-1} \sqrt{\mu_i} |ii\rangle \quad (25)$$

with μ being a vector consisting of the Schmidt coefficients $\mu_i > 0$, and consider its mixture with white noise

$$\rho_\mu(p) = p|\psi_\mu\rangle\langle\psi_\mu| + (1-p)\frac{\mathbb{1} \otimes \mathbb{1}}{d^2} \quad (0 \leq p \leq 1). \quad (26)$$

It is known that this state is entangled iff [26]

$$p \leq p_\mu^{\text{sep}} \equiv \frac{1}{d^2\theta + 1} \quad (27)$$

with $\theta = \max_{i \neq j} \{\sqrt{\mu_i \mu_j}\}$. The application of Λ_A and Λ_B introduced in the previous example to the corresponding subsystems of $\rho_\mu(p)$ leads us to the following quite general class of N -partite states:

$$\rho_{N,\mu}(p) = p|\psi_{N,\mu}\rangle\langle\psi_{N,\mu}| + (1-p)\frac{\mathcal{P}_{d,L} \otimes \mathcal{P}_{d,N-L}}{d^2} \quad (0 \leq p \leq 1), \quad (28)$$

where $|\psi_{N,\mu}\rangle$ is the so-called N -qudit Schmidt state, i.e., a generalization of the N -qudit GHZ state given by

$$|\psi_{N,\mu}\rangle = \sum_{i=0}^{d-1} \sqrt{\mu_i} |i\rangle^{\otimes N}. \quad (29)$$

We thus obtain a quite general class of N -qudit states which are mixtures of the Schmidt states and some particular type of noise whose entanglement is straightforward to characterize via our results: they are genuinely entangled iff the condition (27) is satisfied.

Example 3. The above choice of the isometry V_L is probably the simplest one that one could think of. Now, our aim is to provide a less direct example, in particular one that maps bipartite qudit states into multipartite qubit ones. Let us consider a particular two-qudit pure state (25) of the form

$$|\varphi\rangle = \frac{1}{\sqrt{\binom{2N}{d-1}}} \sum_{i=0}^{d-1} \sqrt{\binom{N}{i} \binom{N}{d-1-i}} |ii\rangle, \quad (30)$$

and, again, its mixture with white noise as given in Eq. (28). Let us then consider the following isometries,

$$V_N|i\rangle = |D_{N,i}\rangle \quad V'_N|i\rangle = |D_{N,d-1-i}\rangle \quad (i = 0, \dots, d-1), \quad (31)$$

which map the standard basis in \mathbb{C}^d to N -qubit symmetric Dicke states with $N = d - 1$. After applying them to $|\varphi\rangle$ one obtains the following N -qubit pure state,

$$V_N \otimes V'_N |\varphi\rangle = \frac{1}{\sqrt{\binom{2N}{d-1}}} \sum_{i=0}^{d-1} \sqrt{\binom{N}{i} \binom{N}{d-1-i}} |D_{N,i}\rangle |D_{N,d-1-i}\rangle, \quad (32)$$

which with a bit of algebra can be shown to be simply the $2N$ -qubit state with $d - 1$ excitations $|D_{2N,d-1}\rangle$; this is because the factors appearing under the sum are normalization factors of the Dicke states $|D_{N,i}\rangle$ and $|D_{N,d-1-i}\rangle$, and thus (32) is a normalized sum of all $2N$ -qubit kets containing $d - 1$ ones and $d - 1$ zeros, which is nothing but the Dicke state $|D_{2N,d-1}\rangle$.

When applied to the mixture of $|\varphi\rangle$ and the white noise, these isometries give rise to the following $2N$ -qubit noisy Dicke state given by

$$\rho_{2N}(p) = p|D_{2N,d-1}\rangle\langle D_{2N,d-1}| + (1-p)\frac{P_{d-1}^{\text{sym}} \otimes P_{d-1}^{\text{sym}}}{d^2}, \quad (33)$$

where P_{d-1}^{sym} stands for the projection onto the symmetric subspace of the $(d - 1)$ -qubit Hilbert space. As before we can easily decide on the values of p for which this state is genuinely

entangled. From Eq. (27) it follows that the state $\rho_{2N}(p)$ is genuinely entangled for $p > 1/(d^2\theta_{\text{ev/odd}} + 1)$ with

$$\theta_{\text{ev}} = \frac{1}{\binom{2(d-1)}{d-1}} \binom{d-1}{\lfloor \frac{d-1}{2} \rfloor} \binom{d-1}{\lceil \frac{d-1}{2} \rceil} \quad (34)$$

for even d , and

$$\theta_{\text{odd}} = \frac{1}{\binom{2(d-1)}{d-1}} \binom{d-1}{\frac{d-1}{2}} \sqrt{\binom{d-1}{\frac{d-3}{2}} \binom{d-1}{\frac{d+1}{2}}} \quad (35)$$

for odd d .

Let us note that with a little bit more effort one can analogously construct a mixture of an N -qubit Dicke state with an arbitrary number of excitations $k = 0, \dots, N$ and some noise of the above type that is genuinely entangled.

Example 4. For the last example of an application of the method to bipartite states consider another particular two-qubit Bell diagonal state (the isotropic state is also in this class):

$$\rho_{\text{Bell}}(p) = p|\phi_2^+\rangle\langle\phi_2^+| + (1-p)|\phi_2^-\rangle\langle\phi_2^-|, \quad (36)$$

where $|\phi_2^\pm\rangle = 1/\sqrt{2}(|00\rangle \pm |11\rangle)$. One can easily verify that the state is entangled iff $p \neq 1/2$. Using the isometry (18) with any L , we extend this state to the mixture of two GHZ states with opposite relative phases, i.e.,

$$\sigma_{\text{Bell}}(p) = p|\text{GHZ}_{2,N}^{(+)}\rangle\langle\text{GHZ}_{2,N}^{(+)}| + (1-p)|\text{GHZ}_{2,N}^{(-)}\rangle\langle\text{GHZ}_{2,N}^{(-)}|, \quad (37)$$

where $|\text{GHZ}_{2,N}^{(\pm)}\rangle = 1/\sqrt{2}(|0\rangle^{\otimes N} \pm |1\rangle^{\otimes N})$. Clearly, the resulting state is entangled across the bipartite cut induced by the isometries iff $p \neq 1/2$, and, in consequence, this constitutes the region in which it is also GME. Note that the subspace after the extension, which is spanned by $\text{GHZ}^{(+)}$ and $\text{GHZ}^{(-)}$, falls into both categories: it is symmetric and genuinely entangled.

Example 5. We now move to examples of multipartite states and begin with the case $K = 3$. To that end, we consider the following three-qubit density matrix introduced in Ref. [27]:

$$\rho_{ABC} = \frac{1}{8}\mathbb{1}_8 + \frac{1}{8}\sum_{i=1}^3 \left[\frac{1}{3}\mathbb{1}_2 \otimes \sigma_i \otimes \sigma_i - \frac{1}{2}\sigma_i \otimes \mathbb{1}_2 \otimes \sigma_i \right], \quad (38)$$

where σ_i for $i = 1, 2, 3$ are the standard Pauli matrices.

Let us then consider the isometries $\Lambda_i = V_{L_i}(\cdot)V_{L_i}^\dagger$ ($i = 1, 2, 3$), where L_i are integers greater than one and V_L is introduced above. When applied to the subsystems of the state ρ_{ABC} , they give the following N -qubit state:

$$\begin{aligned} \sigma_{\mathbf{A}} &\equiv \Lambda_1 \otimes \Lambda_2 \otimes \Lambda_3(\rho_{ABC}) \\ &= \frac{1}{8}\mathcal{P}_{L_1,2} \otimes \mathcal{P}_{L_2,2} \otimes \mathcal{P}_{L_3,2} \\ &+ \frac{1}{8}\sum_{i=1}^3 \left[\frac{1}{3}\mathcal{P}_{L_1,2} \otimes \Sigma_{L_2,i} \otimes \Sigma_{L_3,i} - \frac{1}{2}\Sigma_{L_1,i} \otimes \mathcal{P}_{L_2,2} \otimes \Sigma_{L_3,i} \right], \end{aligned} \quad (39)$$

where $\mathcal{P}_{L,2}$ are defined above and $\Sigma_{L,i} = V_L \sigma_i V_L^\dagger$ with $i = 1, 2, 3$ are Pauli matrices embedded in the L -qubit Hilbert space. As discussed in Ref. [27], the state ρ_{ABC} is genuinely

entangled, and thus by virtue of Fact 3, the state σ_A is genuinely entangled too.

Example 6. Here, we give yet another illustration of the method in the case of a multipartite state as a departure one. In particular, we consider a K -qubit mixed state with the support in the subspace spanned by the W state,

$$|W_{2,K}\rangle = \frac{1}{\sqrt{K}}(|10\dots 00\rangle + |01\dots 00\rangle + \dots + |00\dots 01\rangle), \tag{40}$$

and its ‘‘complement,’’

$$\begin{aligned} |\hat{W}_{2,K}\rangle &= \frac{1}{\sqrt{K}}(|01\dots 11\rangle + |10\dots 11\rangle + \dots + |11\dots 10\rangle) \\ &= \sigma_x^{\otimes K} |W_{2,K}\rangle. \end{aligned} \tag{41}$$

It is known that any incoherent mixture of these states,

$$\rho_{A_1 A_2 \dots A_K} = p|W_{2,K}\rangle\langle W_{2,K}| + (1-p)|\hat{W}_{2,K}\rangle\langle \hat{W}_{2,K}|, \tag{42}$$

is genuinely entangled for any K [28]. Consider now isometries $V : \mathbb{C}^2 \rightarrow (\mathbb{C}^2)^{\otimes L}$ acting as follows:

$$|0\rangle_{A_i} \longrightarrow |W_{2,L}\rangle_{A_i^{(L)}}, \tag{43}$$

$$|1\rangle_{A_i} \longrightarrow |\hat{W}_{2,L}\rangle_{A_i^{(L)}}, \tag{44}$$

where $A_i^{(L)} := A_{(i-1)L+1} \dots A_{iL}$. As in Example 4, this isometry sends to a subspace which is both symmetric and genuinely entangled. An application of $V^{\otimes K}$ to the state (42) results in a genuinely entangled N -partite ($N = LK$) state:

$$\begin{aligned} \sigma_A &= V^{\otimes K} \rho_{A_1 A_2 \dots A_K} (V^\dagger)^{\otimes K} \\ &= p|(W_{\hat{W}})_{2,N}\rangle\langle (W_{\hat{W}})_{2,N}|_A + (1-p)|(\hat{W}_{\hat{W}})_{2,N}\rangle\langle (\hat{W}_{\hat{W}})_{2,N}|_A, \end{aligned} \tag{45}$$

where

$$\begin{aligned} |(W_{\hat{W}})_{2,N}\rangle_A &= \frac{1}{\sqrt{K}} \sum_{i=1}^K \left[|\hat{W}_{2,L}\rangle_{A_i^{(L)}} \otimes \left(\bigotimes_{\substack{f=1 \\ f \neq i}}^K |W_{2,L}\rangle_{A_f^{(L)}} \right) \right], \\ |(\hat{W}_{\hat{W}})_{2,N}\rangle_A &= \frac{1}{\sqrt{K}} \sum_{i=1}^K \left[|W_{2,L}\rangle_{A_i^{(L)}} \otimes \left(\bigotimes_{\substack{f=1 \\ f \neq i}}^K |\hat{W}_{2,L}\rangle_{A_f^{(L)}} \right) \right]. \end{aligned} \tag{46}$$

Concluding this section we note an interesting feature of the states constructed within our approach. Namely, their entanglement properties do not depend on the number of particles in the system; i.e., once the starting state is known to be (genuinely) entangled, the resulting one is guaranteed to be GME regardless of the number of parties after the extension. This is in contrast to the situation occurring in the case of many important classes of states not covered by the current approach, e.g., the mixture of the GHZ state and the white noise (see Ref. [29]).

IV. APPLICATION TO (UN)STEERABILITY AND (NON)LOCALITY OF GME STATES

Importantly, apart from merely providing examples of GME states, our construction can also be applied to provide further instances of multipartite states that are not genuinely multipartite nonlocal. We will also apply the method to present unsteerability of GME states.

A. Multipartite nonlocality

Before being able to state our results we need some preparation. Assume again that the parties share some state ρ_A , but now on their share of this state, each party A_i performs a measurement M_i with measurement operators denoted by $M_{a_i}^{(i)}$, where a_i labels the outcomes. Recall that in order to form a quantum measurement the operators $M_{a_i}^{(i)}$ must be positive and sum up to the identity $\mathbb{1}_d$. If these operators are supported on orthogonal subspaces, i.e., $M_{a_i}^{(i)} M_{a'_i}^{(i)} = \delta_{a_i a'_i} M_{a_i}^{(i)}$, we call the corresponding measurement *projective* (PM). Otherwise, it is called a *generalized* measurement (GM; also called POVM).

These measurements on ρ_A give rise to the probability distribution

$$\begin{aligned} p(\mathbf{a}|\mathbf{M}) &:= p(a_1, \dots, a_N | M_1, \dots, M_N) \\ &= \text{tr}[(M_{a_1}^{(1)} \otimes \dots \otimes M_{a_N}^{(N)}) \rho_A], \end{aligned} \tag{47}$$

where each $p(\mathbf{a}|\mathbf{M})$ denotes the probability of obtaining $\mathbf{a} := a_1, \dots, a_N$ upon measuring $\mathbf{M} := M_1, \dots, M_N$.

In full analogy to the notion of K -separability let us then imagine that for any choice of the measurements M_1, \dots, M_N , the probability distribution $p(\mathbf{a}|\mathbf{M})$ admits the following convex combination:

$$\begin{aligned} p(\mathbf{a}|\mathbf{M}) &= \sum_{S_K \in \mathcal{S}_K} p_{S_K} \int_{\Omega_{S_K}} d\lambda \omega_{S_K}(\lambda) p_1(\mathbf{a}_{S_1} | \mathbf{M}_{S_1}, \lambda) \dots p_K(\mathbf{a}_{S_K} | \mathbf{M}_{S_K}, \lambda). \end{aligned} \tag{48}$$

Here the sum goes over all K -partitions $S_K \in \mathcal{S}_K$, p_{S_K} and ω_{S_K} are probability distributions parameterized by the K -partitions S_K 's, and Ω_{S_K} 's are sets over which λ 's are distributed. Moreover, $p_k(\mathbf{a}_{S_k} | \mathbf{M}_{S_k})$, called a *response function*, is the probability that the parties belonging to the set S_k obtain results \mathbf{a}_{S_k} upon measuring \mathbf{M}_{S_k} .

Now, if we do not impose any conditions on the nature of the response function $p_i(\mathbf{a}_{S_i} | \mathbf{M}_{S_i})$ (quantum, nonsignaling, etc.), except that they form a proper probability distribution, i.e., they are nonnegative and sum up to one, Eq. (48) gives the definition of K -locality of the state ρ_A due to Svetlichny [30]. Analogously to entanglement, if $K = N$ we call ρ_A *fully local*, while if $K = 2$ it is said to be *bilocal*. If we consider a certain K -partition S_K we omit the sum over the partitions in Eq. (48) and talk about K -locality with respect to S_K . States that are local are also said to have a *local hidden variable* (LHV) model (of the corresponding type) or simply a local model. Finally, if $p(\mathbf{a}|\mathbf{M})$ is not bilocal for any choice of the measurements, then we say that ρ_A is *genuinely multipartite nonlocal* (GMN).

The intuition behind Svetlichny's definition is that the correlations that are not fully local might still display locality

if some parties are grouped together, in the sense that their statistics can be described by global probability distributions of any nature. In particular, they do not need to be quantum, i.e., obtainable via Born’s rule. It should be emphasized that within this approach each party still has only access to their subsystem of ρ_A , or, in other words, joint measurements of more than one particle are not allowed. However, although at first sight quite natural, the definition of Svetlichny has been shown to be inconsistent with the operational interpretation of nonlocality in multipartite systems [14,15]. One of the ways to fix this problem is to impose that all response functions in (48) obey the no-signaling principle. This gives one of the operational definitions of K -locality proposed in [14,15]: ρ_A is K -local if for any choice of the measurements the corresponding probability distribution $p(\mathbf{a}|\mathbf{M})$ admits the form (48) in which all response functions $p_k(\mathbf{a}_k|M_{S_k})$ are nonsignaling.

Although, as already said, the Svetlichny definition is not consistent with the operational interpretation of nonlocality in multipartite systems, we use it because it allows us to state our results in a general way. Still, our construction is also capable of providing states that are GME but not GMN even if the above operational definition of nonlocality is used. Later, we provide some illustrative examples.

Let us now get back to our construction and consider a K -partite state $\rho_{A_1\dots A_K}$, but this time we additionally assume that it has a fully local model for generalized measurements. An example of such a state for $K = 2$ would be the isotropic states $\rho_{\text{iso}}(p)$ defined in Eq. (17), or in the general multipartite scenario the one constructed in Ref. [16]. Consider then an arbitrary K -partition $S_1|\dots|S_N$ of N parties and define a collection of K maps

$$\Lambda_i : \mathcal{B}(\mathcal{H}_{A_i}) \rightarrow \mathcal{B}(\mathcal{H}_{S_i}), \quad 1 \leq i \leq K, \quad (49)$$

with $\mathcal{H}_{S_i} = \mathcal{H}_{|S_i|,d'}$ and $|S_1| + \dots + |S_K| = N > K$. As previously, we assume these maps to be trace-preserving; however, instead of assuming that they are positive we impose their dual maps $\Lambda_i^\dagger : \mathcal{B}(\mathcal{H}_{|S_i|,d'}) \rightarrow \mathcal{B}(\mathcal{H}_{A_i})$ to be positive on products of positive operators (PPPO).² The operations defined in Eq. (49) will serve us to extend the state $\rho_{A_1\dots A_K}$ to an N -partite one just as it was in the previous sections.

The following statement was made by Barrett in [31] and later generalized in [13].

Theorem 5. Let $\rho_{A_1\dots A_K}$ be a state acting on $\mathcal{H}_{d,K}$ that has a fully local model for generalized measurements. Then, for any collection of trace-preserving maps $\Lambda_i : \mathcal{B}(\mathcal{H}_{A_i}) \rightarrow \mathcal{B}(\mathcal{H}_{S_i})$ whose dual maps Λ_i^\dagger are PPPO and such that $\otimes_{i=1}^K \Lambda_i(\rho_{A_1\dots A_K}) \geq 0$, the N -partite state $\sigma_A = \otimes_{i=1}^K \Lambda_i(\rho_{A_1\dots A_K})$ is K -local with respect to the K -partition $S_1|\dots|S_K$.

The proof of this statement can be found in the Supplemental Material of Ref. [13]. Note that originally it was proven there assuming that Λ_i are all quantum channels, i.e., completely positive trace-preserving maps; however, this assumption can be relaxed as we do here, but remembering that we always need

to guarantee that $\otimes_{i=1}^K \Lambda_i(\rho_{A_1\dots A_K}) \geq 0$. One also has to bear in mind that the dual map of a trace-preserving positive map is also positive and moreover unital, i.e., preserves the identity.

A combination of this fact with our construction of multipartite genuinely entangled states stated in Theorem 4 gives rise to a method of generation of GME states that are not GMN. Concretely, we have the following statement.

Theorem 6. Let $\rho_{A_1\dots A_K}$ be a K -partite quantum state acting on $\mathcal{H}_{d,K}$ that has a fully local model for generalized measurements. Let then $\Lambda_i : \mathcal{B}(\mathcal{H}_{A_i}) \rightarrow \mathcal{B}(\mathcal{V}_i)$ be a collection of isometries with output subspaces \mathcal{V}_i being either symmetric or GES. Then, the N -partite state

$$\sigma_A = (\Lambda_1 \otimes \dots \otimes \Lambda_K)(\rho_{A_1\dots A_K}) \quad (50)$$

is GME and K -local with respect to the K -partition induced by Λ_i ’s.

Proof. It is direct to see that the dual map of an isometry is PPPO and therefore it follows from Theorem 5 that the state σ_A has a K -local model for generalized measurements with respect to the K -partition induced by the maps Λ_i . Then, by virtue of Theorem 4, the fact that $\rho_{A_1\dots A_K}$ is GME implies that so is σ_A . ■

Now, using the above result, we demonstrate that some of the states introduced in Sec. III C are GME but not GMN according to the Svetlichny definition of nonlocality because they all have a bilocal model for generalized measurements. Let us consider each example separately from this perspective.

Example 1. The class of N -qudit states from Eq. (19) was already considered in Ref. [13] also in the context of nonlocality. For completeness, let us recall these results.

It was proven in Ref. [32] that the isotropic states (17) admit a local model for generalized measurements for any p obeying

$$p \leq p_{\text{GM}} \equiv \frac{(3d-1)(d-1)^{d-1}}{(d+1)d^d}. \quad (51)$$

Hence, the N -partite states $\rho_N(p)$ [Eq. (19)] are genuinely entangled but not genuinely nonlocal for any $1/(d+1) < p \leq p_{\text{GM}}$.

The same reasoning applies to the states $\hat{\rho}_{2n}(p)$ with the only difference now that $d = 2^{n-2}$.

Example 2. Let us now pass to a more general class of N -qudit states given in Eq. (28). It was shown in Ref. [32] that the two-qudit mixed states (26) have a local model for generalized measurements for

$$p \leq \tilde{p}_{\text{GM}} \equiv \frac{p_{\text{GM}}}{(1-p_{\text{GM}})(d-1)+1}, \quad (52)$$

and thus, via our construction, the N -partite states are bilocal according to the Svetlichny definition of nonlocality for the same values of p . So, among all states $\rho_{N,\mu}(p)$ defined by Eq. (28) and parametrized by the vector μ of Schmidt coefficients, there are GME states that are bilocal if

$$\tilde{p}_{\text{GM}} > 1/(d^2\theta_\mu + 1), \quad (53)$$

where, to recall, $\theta_\mu = \max_{i \neq j} \{\sqrt{\mu_i \mu_j}\}$. In fact, it is not difficult to find such μ . In particular, due to the fact that $\tilde{p}_{\text{GM}} \geq (3d-1)/[4d(d+1)]$, one sees that the condition (53) is satisfied whenever $\theta_\mu > (1/d^2)[(4d^2+d+1)/(3d-1)]$ and, clearly, entangled pure states $|\psi_\mu\rangle$ for which this last inequality is satisfied do exist.

²Recall that a linear map $\Lambda : \mathcal{B}((\mathbb{C}^d)^{\otimes N}) \rightarrow \mathcal{B}(\mathbb{C}^d)$ is termed positive on products of positive operators if $\Lambda(P_1 \otimes \dots \otimes P_N) \geq 0$ for any sequence of positive operators P_i [40].

Let us finally mention that there are bipartite quantum states admitting local models for generalized measurements for larger values of p than (52) for which our construction can be applied. As shown in Ref. [32] the following mixture,

$$\tilde{\rho}_\mu(p) = p|\psi_\mu\rangle\langle\psi_\mu| + (1-p)\rho_A \otimes \frac{\mathbb{1}_d}{d}, \quad (54)$$

where $|\psi_\mu\rangle$ is a pure state defined in Eq. (25) and ρ_A is its single-party marginal, has a local model for all measurements for any $p \leq p_{GM}$.

Example 3. Unfortunately for the class of states (33) the condition (53) is not satisfied and therefore we cannot claim his state to be an example of a GME state that is not GMN.

Example 4. The states (36) violate the CHSH inequality and in consequence are nonlocal in the whole region of entanglement [33]. In turn, the states (37) are not bilocal.

Example 5. As shown in Ref. [27] the tripartite state (38) has a hybrid local model, i.e., for PMs on A and POVMs on B and C . For this reason the GME state (39) cannot be claimed to be 3-local for any kind of measurements. However, if we keep the party A untouched, i.e., map it identically to itself or unitarily conjugate it, we obtain a GME state which has a 3-local model for projective measurements on A and general measurements for the rest of the parties. This possibility has been already noted in [34].

Importantly, the original state can be extended to a qutrit-qubit-qubit state which does have a local model for general measurements still being genuinely entangled [35]. Such a state then, after the application of the extending maps, will be 3-local for all measurements.

Example 6. This state is known to be nonlocal for $p \neq 1/2$. The case $p = 1/2$ remains, to the best of our knowledge, unsolved, although the results of Ref. [28] might indicate that for this value of the parameter they are (fully) local.

Consequently, we provide more examples, over those provided in Ref. [13], of N -partite quantum states giving rise to the inequivalence between entanglement and nonlocality in the multiparty case.

This inequivalence persists if one considers operational definitions of nonlocality formulated in Refs. [14]. For completeness, we recall the proof of this fact from Ref. [13]. Consider those entangled states that have a local model for generalized measurements, meaning that

$$p_\rho(a,b|M_A,M_B) = \int_\Omega d\lambda \omega(\lambda) p_\rho(a|M_A,\lambda) p_\rho(b|M_B,\lambda) \quad (55)$$

holds for any M_A and M_B in which one of the response functions, say the one on Bob's side, is quantum; that is, it can be written as $p_\rho(b|M_B,\lambda) = \text{Tr}[\sigma_\lambda M_b]$, where σ_λ is some quantum state representing the hidden variable λ and $\{M_b\}$ are the measurement operators of the measurement M_B . We have added subscripts to the response functions to stress for which states the model is considered. We then consider two isometries

$$\Lambda_{A \rightarrow A_1} : \mathcal{B}(\mathbb{C}^d) \rightarrow \mathcal{B}(\mathbb{C}^d), \quad \Lambda_{B \rightarrow \bar{S}} : \mathcal{B}(\mathbb{C}^d) \rightarrow \mathcal{B}(\mathcal{V}_2). \quad (56)$$

The first one is trivial as its output space is the same as the initial one (in fact it is just a unitary conjugation), whereas the second one maps to some subspace \mathcal{V}_2 of an $(N-1)$ -partite

Hilbert space corresponding to parties A_2, A_2, \dots, A_N . Their application to $\rho_{AB} \in \mathcal{B}(\mathbb{C}^d \otimes \mathbb{C}^d)$ gives us an N -partite state $\sigma_A = (\Lambda_{A \rightarrow A_1} \otimes \Lambda_{B \rightarrow \bar{S}})(\rho_{AB})$ which, according to Theorem 6, is GME and has a bilocal model (48) with respect to the bipartition $A_1|A_2 \dots A_N$ obtained from the local model (56), which we can explicitly write as

$$\begin{aligned} p_\sigma(\mathbf{a}|\mathbf{M}) &= \int_\Omega d\lambda \omega(\lambda) p_\sigma(a_1|\hat{M}_1,\lambda) p_\sigma(a_2, \dots, a_N|\hat{M}_2, \dots, \hat{M}_N,\lambda), \end{aligned} \quad (57)$$

where the response function of the party A_1 is defined as $p_\sigma(a_1|\hat{M}_1,\lambda) = p_\rho(a_1|M_A,\lambda)$ with the measurement operators of the measurement M_A given by $M_a = \Lambda_{A_1 \rightarrow A}^\dagger(\hat{M}_a)$, whereas the response function corresponding to the parties A_2, \dots, A_N is defined as $p_\sigma(a_2, \dots, a_N|\hat{M}_2, \dots, \hat{M}_N,\lambda) = p(\mathbf{a}|M_B,\lambda)$, where $\mathbf{a} := a_2, \dots, a_N$ and the measurement operators of the measurement $M_B = \{M_a\}_a$ are given by

$$M_a = \Lambda_{\bar{S} \rightarrow B}^\dagger(M_{a_2}^{(2)} \otimes \dots \otimes M_{a_N}^{(N)}). \quad (58)$$

To show that the model is in agreement with the operational definitions of nonlocality, it suffices to show that the response function $p_\sigma(a_2, \dots, a_N|\hat{M}_2, \dots, \hat{M}_N,\lambda)$ obeys the no-signaling principle. To this end, we exploit the fact that Bob's response function in the model (55) has a quantum realization, meaning that

$$\begin{aligned} p_\sigma(a_2, \dots, a_N|\hat{M}_2, \dots, \hat{M}_N,\lambda) &= \text{Tr}[\sigma_\lambda M_a] \\ &= \text{Tr}[\sigma_\lambda \Lambda_{\bar{S} \rightarrow B}^\dagger(M_{a_2}^{(2)} \otimes \dots \otimes M_{a_N}^{(N)})] \\ &= \text{Tr}[\Lambda_{B \rightarrow \bar{S}}(\sigma_\lambda)(M_{a_2}^{(2)} \otimes \dots \otimes M_{a_N}^{(N)})]. \end{aligned} \quad (59)$$

Due to the fact that $\Lambda_{B \rightarrow \bar{S}}$ is a positive trace-preserving map, $\Lambda_{B \rightarrow \bar{S}}(\sigma_\lambda)$ is a valid quantum state, and therefore $p_\sigma(a_2, \dots, a_N|\hat{M}_2, \dots, \hat{M}_N,\lambda)$ is a quantum response function, meaning that it necessarily obeys the nonsignaling principle (see, e.g., Ref. [36]).

To complete the proof let us mention that there exist local models in which one of the response functions is quantum, with the well-known example being the Barrett model [31] for the Werner states [37]. Another example of such a model is the one introduced in Ref. [32] for the isotropic states (17). Thus, the N -partite states given in Eqs. (19) and (28) [in the second case provided that the condition (53) is satisfied] with $L = 1$ (that is, the isometry is applied only to the second subsystem) are examples of GME states that are not GMN according to the operational definitions of nonlocality.

B. Multipartite steering

Interestingly, this last observation suggests that our method can also be used to construct GME states that are unsteerable in a sense we will make precise in this section. This has already been mentioned in [13] but no details have been given regarding this issue. We fill this gap here.

We first recall the notion of steering and begin with the simplest bipartite scenario as it serves as the basis for our main constructions.

In a steering scenario two parties share at the beginning an unknown state $\rho_{AB} \in \mathcal{B}(\mathbb{C}^d \otimes \mathbb{C}^d)$. The question now is whether one of the parties, say Alice (A), by performing some measurements on her share of ρ_{AB} , is able to collapse (steer) Bob's reduced state into different ensembles.

More formally, suppose Alice may perform some predetermined number of generalized measurements $M_x = \{M_a^x\}$, where a enumerates results of the x th measurement (for simplicity we assume all measurements to have the same number of outcomes) and M_a^x are the measurement operators, i.e., $M_a^x \geq 0$ and $\sum_a M_a^x = \mathbb{1}_d$ for each x . The unnormalized Bob's state after the result a of the x th measurement has been obtained reads

$$\varrho_{a|x}^B = \text{tr}_A[(M_a^x \otimes \mathbb{1}_B)\rho_{AB}]. \quad (60)$$

The collection $\{\varrho_{a|x}^B\}_{a,x}$ is referred to as an *assemblage*. Now, we say that the assemblage $\{\varrho_{a|x}^B\}_{a,x}$ is *unsteerable* from Alice to Bob, shortly $A \rightarrow B$ unsteerable, if the above can be written as

$$\varrho_{a|x}^B = \int_{\Omega} d\lambda \omega(\lambda) p(a|x, \lambda) \sigma_{\lambda}^B, \quad (61)$$

where Ω is again the set of hidden variables, $\omega(\lambda)$ is some probability density over Ω , $p(a|M_A, \lambda)$ is a probability distribution, called as previously the response function of party A , and σ_{λ}^B are some quantum states.

If the opposite holds we say that the given assemblage is $A \rightarrow B$ *steerable*. Further, if *all* possible assemblages are unsteerable (to reduce the clutter, when the direction of steering is clear we omit $X \rightarrow Y$) we say that the state itself is unsteerable and if there exists a steerable assemblage we call the state steerable. Unsteerable assemblages (states) are said to have a local hidden state model (LHS)—the name stemming directly from the form of (61).

Not surprisingly, steering cannot take place when the initial state is separable, i.e., $\rho_{AB} = \sum_{\lambda} p_{\lambda} \varrho_{\lambda}^A \otimes \gamma_{\lambda}^B$. In such case it is enough to take $p(a|x, \lambda) := \text{tr} M_a^x \varrho_{\lambda}^A$ and it is immediate to realize that the resulting $\varrho_{a|x}^B$ assumes the form of Eq. (61). Entanglement is thus a necessary condition for steering and the presence of steering certifies entanglement of an unknown state ρ_{AB} . Nevertheless, it is not sufficient: although all separable states are unsteerable, some entangled states also have an underlying LHS. These notions are thus inequivalent. In fact, steering as a type of correlation can be placed strictly between entanglement and nonlocality. As a side note, note that the definition of steering introduces asymmetry into the scenario as it distinguishes the roles of the parties. *A priori*, there is no guarantee that this asymmetry remains at the fundamental level, i.e., some states are steerable from Alice to Bob [Eq. (61) does not hold] but not in the opposite direction [Eq. (61) with the parties exchanged always holds]. It turns out that it is indeed the case: there are known examples of states which are only one-way steerable [39].

In the modern approach, steering is considered within the paradigm of (one-sided) device-independent quantum information processing. While it is assumed that Bob's measurements (with the roles of the parties in the formulation we have presented here) are well characterized and trusted, Alice's measurements are treated as black boxes performing unspecified POVMs M_x . Bob can perform full state tomography and

learn the states $\varrho_{a|x}^B$ and later basing on this knowledge verify whether Alice indeed might have steered his share of the state.

Let us now move to the multipartite case, where the situation clearly becomes more involved. It is not our goal to consider all steering scenarios possible in the multipartite setting (see Ref. [38]). We only focus on the case of relevance for future purposes in the present paper, which is the scenario in which a group of L parties perform (untrusted) measurements and the question is whether this might lead to the lack of a LHS model, in the sense of Eq. (61), on the remaining $N - L$ parties.

Let us then consider again N parties sharing a quantum state $\rho_{\mathbf{A}} \in \mathcal{B}((\mathbb{C}^d)^{\otimes N})$. Let the parties be split into two groups according to a given bipartition $S|\bar{S}$. For simplicity and no loss of generality we assume that $S = A_1, \dots, A_L$ and $\bar{S} = A_{L+1}, \dots, A_N$. The number L varies from 1 to $N - 1$ depending on the concrete situation.

Suppose now that the i th party from S may perform local measurements $M_{x_i}^{(i)} = \{M_{a_i}^{x_i}\}$ with measurement operators $M_{a_i}^{x_i}$; x_i 's enumerate the measurements and the outcomes are labeled a_i . The unnormalized postmeasurement states on \bar{S} now read

$$\varrho_{\mathbf{a}_S|\mathbf{x}_S}^{\bar{S}} = \text{Tr}_S[(M_{a_1}^{x_1} \otimes \dots \otimes M_{a_L}^{x_L} \otimes \mathbb{1}_{\bar{S}})\rho_{\mathbf{A}}], \quad (62)$$

where $\mathbf{a} := a_1 \dots a_L$ and $\mathbf{x}_S := x_1, \dots, x_L$.

The terminology now is the same as in the bipartite case. The collection $\{\varrho_{\mathbf{a}_S|\mathbf{x}_S}^{\bar{S}}\}_{\mathbf{a}_S, \mathbf{x}_S}$ is called the assemblage. It is said to be $S \rightarrow \bar{S}$ unsteerable if there is a decomposition of the form

$$\varrho_{\mathbf{a}_S|\mathbf{x}_S}^{\bar{S}} = \int_{\Omega} d\lambda \omega(\lambda) p(\mathbf{a}_S|\mathbf{x}_S, \lambda) \sigma_{\lambda}^{\bar{S}}, \quad (63)$$

where $\sigma_{\lambda}^{\bar{S}}$ are some states (called as previously hidden) acting on the Hilbert space corresponding to the group \bar{S} , whereas $p(\mathbf{a}_S|\mathbf{x}_S, \lambda)$ is a response function corresponding to parties belonging to S ; Ω is the set of hidden variables and $\omega(\lambda)$ a probability density over Ω . It is worth noting at this point that the hidden states $\sigma_{\lambda}^{\bar{S}}$ are arbitrary in the sense that no separability condition is imposed on them, although the parties from \bar{S} are spatially separated. If there is no decomposition (63) for the assemblage, it is called $S \rightarrow \bar{S}$ steerable. If for some choice of measurements the resulting assemblage is $S \rightarrow \bar{S}$ steerable the state $\rho_{\mathbf{A}}$ is called $S \rightarrow \bar{S}$ steerable. Otherwise, it is said to be $S \rightarrow \bar{S}$ unsteerable.

Let us now demonstrate that the methods from Sec. III B may be directly linked with a construction of genuinely multipartite entangled states which are unsteerable for a given bipartition. The result relies on the observation made by some of us in Ref. [39]. We recall it here in a version adapted to our considerations. Let us take, analogously to Sec. IV A, a state ρ_{AB} and two trace-preserving maps $\Lambda_{A \rightarrow S}$ and $\Lambda_{B \rightarrow \bar{S}}$ and assume $\Lambda_{A \rightarrow S}$ to have the dual³ map PPPO and $\Lambda_{B \rightarrow \bar{S}}$ to

³Given the linear map $\Lambda : \mathcal{B}(\mathcal{H}) \rightarrow \mathcal{B}(\mathcal{K})$ its dual is defined to be the linear map $\Lambda^{\dagger} : \mathcal{B}(\mathcal{K}) \rightarrow \mathcal{B}(\mathcal{H})$ satisfying $\text{Tr}[X\Lambda(Y)] = \text{Tr}[\Lambda^{\dagger}(X)Y]$ for any $X \in \mathcal{B}(\mathcal{K})$ and $Y \in \mathcal{B}(\mathcal{H})$. Recall that if Λ is positive (in particular completely positive), its dual Λ^{\dagger} is also positive. Moreover, if Λ is trace-preserving, i.e., $\text{Tr}[\Lambda(X)] = \text{Tr}X$ for any X , the dual map Λ^{\dagger} is unital, i.e., $\Lambda^{\dagger}(\mathbb{1}_{\mathcal{K}}) = \mathbb{1}_{\mathcal{H}}$ with $\mathbb{1}_{\mathcal{X}}$ being the identity operator acting on \mathcal{X} .

be positive. Assuming then that $(\Lambda_{A \rightarrow A_1} \otimes \Lambda_{B \rightarrow \bar{S}})(\rho_{AB}) \geq 0$, we have the following fact (see also Ref. [39]).

Fact 4. Let $\rho_{AB} \in \mathcal{B}(\mathcal{H}_{2,d})$ be $A \rightarrow B$ unsteerable. Then, for any pair of trace-preserving positive maps $\Lambda_{A \rightarrow S}$ and $\Lambda_{B \rightarrow \bar{S}}$ such that $\Lambda_{B \rightarrow \bar{S}}$ has the dual map PPPO and $(\Lambda_{A \rightarrow S} \otimes \Lambda_{B \rightarrow \bar{S}})(\rho_{AB}) \geq 0$, the N -partite state

$$\sigma_A = (\Lambda_{A \rightarrow S} \otimes \Lambda_{B \rightarrow \bar{S}})(\rho_{AB}) \quad (64)$$

is $S \rightarrow \bar{S}$ unsteerable.

The proof of this fact can be found in Ref. [39]; however, for completeness we also provide it in the Appendix. We just mention here the origin of the requirement of the dual of $\Lambda_{B \rightarrow \bar{S}}$ to be PPPO. This stems from the fact that an application of this map to the products of local measurement operators on \bar{S} must result in positive operators, as the latter constitute a generalized measurement.

To construct example multipartite states that are genuinely entangled and at the same time $S \rightarrow \bar{S}$ unsteerable, let now

$$\begin{aligned} \Lambda_{A \rightarrow S} &: B(\mathbb{C}^d) \rightarrow B(\mathcal{V}_S), \\ \Lambda_{B \rightarrow \bar{S}} &: B(\mathbb{C}^d) \rightarrow B(\mathcal{V}_{\bar{S}}) \end{aligned} \quad (65)$$

be two isometries with \mathcal{V}_S and $\mathcal{V}_{\bar{S}}$ being subspaces in $\mathcal{H}_{d',L}$ and $\mathcal{H}_{d',N-L}$, respectively, that are either symmetric or genuinely entangled. Then, we have the following fact.

Fact 5. Let ρ_{AB} be entangled but $A \rightarrow B$ unsteerable. For any pair of the isometries (65) the N -partite state $\sigma_A = [\Lambda_{A \rightarrow S} \otimes \Lambda_{B \rightarrow \bar{S}}](\rho_{AB})$ is GME and $S \rightarrow \bar{S}$ unsteerable.

Proof. From Fact 4 we have that the state σ_A is $S \rightarrow \bar{S}$ unsteerable, whereas from previous facts that it is GME. ■

Thus, some of the multipartite states introduced in Sec. III C are not only $S|\bar{S}$ local but also $S \rightarrow \bar{S}$ unsteerable.

To have a definition of unsteerability in the multipartite case à la definition of locality of Refs. [14], one needs to assume that the response function $p(\mathbf{a}_S|\mathbf{x}_S, \lambda)$ is nonsignaling, and accordingly assume that $L = 1$ in the above construction.

V. CONCLUSION

In Ref. [13] we outlined a method of generating genuinely entangled N -partite states from K -partite genuinely entangled ones with $K < N$. The aim of the present work is to describe this method in greater detail and, more importantly, to significantly generalize it. In order to achieve this goal we provide quite general entanglement criteria allowing one to check whether a given multiparty state is genuinely entangled. In the particular case of $K = 2$ these criteria are simple to formulate: if an N -partite state is entangled across certain bipartition $S|\bar{S}$ and its parts corresponding to S and \bar{S} are supported on some genuinely entangled subspace or the symmetric one, then this state is genuinely entangled.

We then apply our method to some known classes of bipartite and multipartite entangled states obtaining examples of mixed N -partite states that are genuinely entangled. At the same time, also generalizing the results of Ref. [13], we demonstrate that with the aid of our method we can construct further examples of N -partite genuinely entangled states which are not genuinely nonlocal. These novel classes of states provide further support for the statement made in Ref. [13]

(see also Ref. [16]) that entanglement and nonlocality are inequivalent notions in the multiparty case.

Our research provokes several natural questions. For instance, it would be interesting to see whether with the aid of our method one can create further interesting classes of multipartity states or whether our entanglement criteria could be used to prove that some existing classes of states are genuinely entangled. On the other hand, it is of interest to see whether the classes of genuinely entangled states we construct admit more restrictive local models, in particular, the fully local one.

From another perspective, one could also investigate how the ideas presented here could be combined with other approaches to the construction of large quantum states from smaller ones such as the fusion-type techniques that allow for creation of GHZ states [41], cluster states [42], or the W states (see, e.g., Refs. [43–45]). It would be of interest to see whether such a combination would account for more general setups.

APPENDIX: PROOFS

Here we provide the proof of Lemma 1 from the main text used in the proof of Facts 3 and 4.

Lemma 1. Let $|\psi\rangle \in \mathcal{H}_{d,N}$ be a pure state which is product across a certain bipartition $T|\bar{T}$. If $P_S^{\text{sym}}|\psi\rangle = |\psi\rangle$ where S is a subset of \mathbf{A} having nontrivial overlaps with T and \bar{T} , i.e., $S \cap T \neq \emptyset$ and $S \cap \bar{T} \neq \emptyset$, then $|\psi\rangle$ is also product with respect to the bipartition $S|\bar{S}$.

Proof. From the assumption that $|\psi\rangle$ is product with respect to $T|\bar{T}$ it follows that $|\psi\rangle = |\psi_T\rangle|\phi_{\bar{T}}\rangle$. Let us then consider two cases: (i) either T or \bar{T} is contained in S ; (ii) none them is contained in S .

Case (i). For concreteness, but without any loss of generality, we assume that T is contained in S . Then, we write the vector $|\phi_{\bar{T}}\rangle$ in its Schmidt decomposition with respect to the bipartition $[\bar{T} \cap S]|\bar{T}'$ with $\bar{T}' = \bar{T} \setminus (\bar{T} \cap S)$ as

$$|\phi_{\bar{T}}\rangle = \sum_i \sqrt{\lambda_i} |\phi_{\bar{T} \cap S}^i\rangle |\omega_{\bar{T}'}^i\rangle, \quad (A1)$$

where λ_i are the Schmidt coefficients, and $|\phi_{\bar{T} \cap S}^i\rangle$ and $|\omega_{\bar{T}'}^i\rangle$ are some orthonormal bases defined on $\bar{T} \cap S$ and \bar{T}' , respectively. The condition $P_S^{\text{sym}}|\psi\rangle = |\psi\rangle$ implies then that for any i , the following identity

$$P_S^{\text{sym}}|\psi_T\rangle|\phi_{\bar{T} \cap S}^i\rangle = |\psi_T\rangle|\phi_{\bar{T} \cap S}^i\rangle \quad (A2)$$

is satisfied. This, by virtue of the results of Refs. [22,23] implies that all vectors $|\psi_T\rangle|\phi_{\bar{T} \cap S}^i\rangle$ are fully product; i.e., they can be written as

$$|\psi_T\rangle|\phi_{\bar{T} \cap S}^i\rangle = |e_i\rangle^{\otimes |S|}, \quad (A3)$$

with $|e_i\rangle$ being some qudit vectors. In fact, the vectors $|e_i\rangle$ can differ only by a phase. To see that, it is enough to trace out the $\bar{T} \cap S$ part of (A3), which gives $|\psi_T\rangle\langle\psi_T| = |e_i\rangle\langle e_i|^{\otimes |T|}$ for any i , meaning that they are all equal up to some phase (there

are clearly some relations between these phases, but they are not important for what follows). As a result,

$$|\psi_T\rangle|\phi_{\bar{T}\cap S}^i\rangle = e^{i\delta_i}|e\rangle^{\otimes|S|}. \quad (\text{A4})$$

Substituting (A3) into (A1) one finally sees that $|\psi\rangle$ is product with respect to $S|\bar{S}$. In fact, it is even fully product on the subspace S .

Case (ii). Let us expand both vectors $|\psi_T\rangle$ and $|\phi_{\bar{T}}\rangle$ as

$$|\psi_T\rangle = \sum_i \sqrt{\lambda_i} |\psi_{T\cap S}^i\rangle |\omega_{\bar{T}'}^i\rangle \quad (\text{A5})$$

and

$$|\phi_{\bar{T}}\rangle = \sum_i \sqrt{\gamma_i} |\phi_{\bar{T}\cap S}^i\rangle |\omega_{\bar{T}'}^i\rangle, \quad (\text{A6})$$

where $|\omega_{\bar{T}'}^i\rangle$ and $|\omega_{\bar{T}'}^i\rangle$ are some orthonormal bases defined on $T \setminus (T \cap S)$ and $\bar{T} \setminus (\bar{T} \cap S)$. The condition $P_S^{\text{sym}}|\psi\rangle = |\psi\rangle$ implies that for any pair i, j one has [Note that $(T \cap S) \cup (\bar{T} \cap S) = S$.]

$$P_S^{\text{sym}}|\psi_{T\cap S}^i\rangle|\phi_{\bar{T}\cap S}^j\rangle = |\psi_{T\cap S}^j\rangle|\phi_{\bar{T}\cap S}^i\rangle. \quad (\text{A7})$$

Again, due to the results of [22,23] every vector in the above must be fully product. Moreover, one can check that these fully product vectors may differ only by a phase, so that

$$|\psi_{T\cap S}^i\rangle|\phi_{\bar{T}\cap S}^j\rangle = e^{i\delta_{ij}}|e\rangle^{\otimes|S|}, \quad (\text{A8})$$

where δ_{ij} are some phases [note that (A7) imposes some conditions on these phases; however, they are not important for the proof; still they must be such that the state remains product with respect to $T|\bar{T}$]. Putting (A8) into $|\psi_T\rangle|\phi_{\bar{T}}\rangle$ one finally obtains that $|\psi\rangle$ is product with respect to $S|\bar{S}$. In particular it is of the form $|\psi_T\rangle|\phi_{\bar{T}}\rangle = |e\rangle^{\otimes|S|}|\bar{\omega}_{\bar{S}}\rangle$, where $|\bar{\omega}_{\bar{S}}\rangle$ is a state defined on $\bar{S} = T' \cup \bar{T}'$. This completes the proof. ■

Let us now provide the proof of Fact 4.

Fact 4. Let $\rho_{AB} \in \mathcal{B}(\mathcal{H}_{2,d})$ be $A \rightarrow B$ unsteerable. Then, for any pair of trace-preserving positive maps $\Lambda_{A \rightarrow S}$ and $\Lambda_{B \rightarrow \bar{S}}$ such that $\Lambda_{B \rightarrow \bar{S}}$ has the dual PPPO and $[\Lambda_{A \rightarrow S} \otimes \Lambda_{B \rightarrow \bar{S}}](\rho_{AB}) \geq 0$, the N -partite state

$$\sigma_A = [\Lambda_{A \rightarrow S} \otimes \Lambda_{B \rightarrow \bar{S}}](\rho_{AB}) \quad (\text{A9})$$

is $S \rightarrow \bar{S}$ unsteerable.

Proof. Let $\Lambda_{S \rightarrow A}^\dagger$ be the dual map of $\Lambda_{A \rightarrow S}$ and define the following operators:

$$\widehat{M}_{a_1}^A = \Lambda_{S \rightarrow A}^\dagger(M_{a_1}^{(1)} \otimes \dots \otimes M_{a_L}^{(L)}). \quad (\text{A10})$$

From the duality of the map in the construction above it immediately follows that the resulting operators form proper POVMs. Unnormalized states after the measurements results a_1 have been obtained upon measuring M_1 by the party A_1 on σ_A [Eq. (A9)] read

$$\begin{aligned} \varrho_{a_1|S}^{\bar{S}} &= \text{Tr}_S[(M_{a_1}^{(1)} \otimes \dots \otimes M_{a_L}^{(L)} \otimes \mathbb{1}_{\bar{S}})\sigma_A] \\ &= \text{Tr}_S[(M_{a_1}^{(1)} \otimes \dots \otimes M_{a_L}^{(L)} \otimes \mathbb{1}_{\bar{S}}) \\ &\quad \times (\Lambda_{A \rightarrow S} \otimes \Lambda_{B \rightarrow \bar{S}})(\rho_{AB})] \\ &= \Lambda_{B \rightarrow \bar{S}}(\text{Tr}_A[\widehat{M}_a^A \rho_{AB}]) \\ &= \Lambda_{B \rightarrow \bar{S}}\left(\sum_\lambda \omega(\lambda) p(a_S|\widehat{M}_A, \lambda) \sigma_\lambda^B\right) \\ &= \sum_\lambda \omega(\lambda) p(a_S|\widehat{M}_A, \lambda) \Lambda_{B \rightarrow \bar{S}}(\sigma_\lambda^B). \quad (\text{A11}) \end{aligned}$$

The penultimate equality, in which $p(a_1|\widehat{M}_A, \lambda)$ is some measurement-dependent probability distribution, is a consequence of $A \rightarrow B$ unsteerability of ρ_{AB} . Postmeasurement states admit thus a decomposition of the form (63), with the hidden states $\{\Lambda_{B \rightarrow \bar{S}}(\sigma_\lambda^B)\}_\lambda$, so the state σ_A is $A_1 \rightarrow \bar{S}$ unsteerable. ■
